

A D'ALEMBERT FORMULA FOR HOPF HYPERSURFACES

THOMAS A. IVEY

ABSTRACT. A Hopf hypersurface in complex hyperbolic space $\mathbb{C}H^n$ is one for which the complex structure applied to the normal vector is a principal direction at each point. In this paper, Hopf hypersurfaces for which the corresponding principal curvature is small (relative to ambient curvature) are studied by means of a generalized Gauss map into a product of spheres, and it is shown that the hypersurface may be recovered from the image of this map, via an explicit parametrization.

INTRODUCTION

A Hopf hypersurface is a real codimension-one submanifold M in a complex space form $\mathbb{C}P^n$ or $\mathbb{C}H^n$ which has the property that the *structure directions* are principal directions at each point. For any hypersurface in these spaces, a tangent vector W is a structure direction if JW is normal to the hypersurface, where J is the complex structure. If we assume that M is oriented, then we may globally define a structure vector field W on M by requiring that JW be the unit normal vector field.

On a Hopf hypersurface, the principal curvature α of the structure direction must be locally constant. (This is due to Maeda [7] for $\mathbb{C}P^n$ and Ki-Suh [6] for $\mathbb{C}H^n$.) Furthermore, Cecil and Ryan [2] showed that every Hopf hypersurface in $\mathbb{C}P^n$ is locally congruent to a tube over a holomorphic submanifold. The radius R of the tube is related to α by the formula $\alpha = (2/r) \cot(2R/r)$, where $4/r^2$ is the ambient holomorphic sectional curvature. Similarly, Montiel [8] showed that Hopf hypersurfaces in $\mathbb{C}H^n$ (with holomorphic sectional curvature $-4/r^2$) are tubes of radius R over holomorphic submanifolds, with $\alpha = (2/r) \coth(2R/r)$. Notice that $|\alpha| > 2/r$ for these tubes; a general construction for Hopf hypersurfaces in $\mathbb{C}H^n$ with ‘small’ α (i.e., $|\alpha| < 2/r$) has been lacking, until now.

The Hopf condition for hypersurfaces in $\mathbb{C}H^n$, when regarded as a system of PDE, changes type depending on α : it is elliptic for ‘large’ α (i.e., $|\alpha| > 2/r$) and hyperbolic for small α . (In the elliptic case, the system is equivalent to the Cauchy-Riemann equations for the holomorphic submanifolds which generate Montiel’s tubes.) The title of this paper is inspired by the fact that, like the standard wave equation $u_{xx} = u_{tt}$, the system for Hopf hypersurfaces with small α is integrable by the *method of Darboux* (see, e.g., Chapter 6 in [3]). For the wave equation, this integrability leads directly to d’Alembert’s formula $u(x, t) = f(x+t) + g(x-t)$ for the general solution, while for Hopf hypersurfaces we can similarly construct the general solution in terms of arbitrary functional data. Indeed, a similar approach has been recently taken by Aledo, Gálvez and Mira [1] for flat surfaces in S^3 .

In an earlier paper [4], Ryan and I showed that a Hopf hypersurface with small α in $\mathbb{C}H^2$ determines, via a kind of generalized Gauss map, a pair of contact curves in S^3 . We also showed that, conversely, the hypersurface may be constructed (without integration) from

Key words and phrases. Hopf hypersurfaces.

an arbitrary pair of contact curves. The main result of this paper (see Theorem 3 below) is a straightforward generalization of this construction to Hopf hypersurfaces in $\mathbb{C}H^n$, with the contact curves being replaced by Legendrian submanifolds in S^{2n-1} . (In all cases, the contact structure on the sphere is the standard one, with contact planes perpendicular to the fibers of the Hopf fibration $S^{2n-1} \rightarrow \mathbb{C}P^{n-1}$.) We also parametrize the Hopf hypersurfaces in $\mathbb{C}H^n$ arising from this construction in terms of two given Legendrian submanifolds. It is this parametrization (27) that we refer to as a d'Alembert formula for Hopf hypersurfaces.

The main vehicle for producing results is the technique of moving frames, and the use of exterior differential systems defined on various frame bundles. We put this machinery in place by discussing moving frames in complex space forms in §1, and examining the exterior differential system for Hopf hypersurfaces in §2. The space $\mathbb{C}H^n$ inherits its geometry as the quotient of the anti-de Sitter space $Q \subset \mathbb{C}^{n+1}$ by a circle action, and the relationship between moving frames on $\mathbb{C}H^n$ and those on Q is laid out in §3. This is used to prove the main result, and also utilized in §4 to obtain the d'Alembert formula.

1. MOVING FRAMES FOR COMPLEX SPACE FORMS

Let X be a simply-connected complex space form of dimension n , with constant holomorphic sectional curvature $4c$. Let $\mathcal{F}$ be the unitary frame bundle of X , with fibration $\rho : \mathcal{F} \rightarrow X$. Sections of this bundle are orthonormal frames $e_1, e_2, \dots, e_{2n}$ which satisfy the relations

$$Je_{2k-1} = e_{2k}, \quad 1 \leq k \leq n.$$

Thus, with respect to this frame, the complex structure on X is represented by the matrix

$$J = \begin{bmatrix} \begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix} & & \\ & \begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix} & \\ & & \ddots \end{bmatrix}. \quad (1)$$

The bundle $\mathcal{F}$ inherits, via pullback from the full orthogonal frame bundle, canonical forms ω^i and connection forms ω_j^i , where $1 \leq i, j \leq 2n$. These satisfy the structure equations

$$d\omega^i = -\omega_j^i \wedge \omega^j, \quad (2)$$

$$d\omega_j^i = -\omega_k^i \wedge \omega_j^k + \Phi_j^i, \quad (3)$$

with curvature 2-forms given by

$$\Phi_j^i = c(J_k^i \omega^k \wedge J_\ell^j \omega^\ell + \omega^i \wedge \omega^j - 2J_j^i \Omega), \quad (4)$$

where

$$\Omega := \omega^1 \wedge \omega^2 + \omega^3 \wedge \omega^4 + \dots + \omega^{2n-1} \wedge \omega^{2n}$$

and we use summation convention for repeated indices from now on. (As explained in §3.1 below, the curvature may be calculated using the fact that X is a quotient of a quadric $Q \subset \mathbb{C}^{n+1}$ by an isometric circle action.) Regarded as components of matrices of size $2n$, the connection and curvature forms take value in $\mathfrak{u}(n) \subset \mathfrak{so}(2n)$, which may be characterized as the subalgebra of matrices commuting with J . In particular, we note that

$$\omega_k^i J_j^k = J_k^i \omega_j^k. \quad (5)$$

Suppose that $(e_1, \dots, e_{2n})$ is a unitary framing defined along a real hypersurface $M \subset X$, adapted so that e_{2n} is the hypersurface normal, and thus e_{2n-1} equals the structure vector W . This framing defines a section $f : M \rightarrow \mathcal{F}$ that satisfies $f^*\omega^{2n} = 0$ and

$$f^*\omega_j^{2n} = A_{jk}\omega^k, \quad 1 \leq j, k \leq 2n-1,$$

where matrix A represents the shape operator of M with respect to the basis for TM provided by $(e_1, \dots, e_{2n-1})$. In what follows, we will identify the framing with the corresponding submanifold $f(M) \subset \mathcal{F}$.

In particular, an adapted framing for a Hopf hypersurface with principal curvature equal to a given constant α will be an integral submanifold of the differential forms

$$\begin{aligned} \theta_0 &:= \omega^{2n}, \\ \theta_1 &:= \omega_{2n-1}^{2n} - \alpha\omega^{2n-1}. \end{aligned}$$

(In other words, these differential forms pull back to vanish on the submanifold $f(M)$.) Conversely, any $(2n-1)$ -dimensional submanifold $\Sigma \subset \mathcal{F}$ that is an integral of θ_0, θ_1 will be generated by an adapted framing along a Hopf hypersurface $M \subset X$, provided that Σ satisfies the independence condition

$$\omega^1 \wedge \omega^2 \wedge \dots \wedge \omega^{2n-1}|_{\Sigma} \neq 0. \quad (6)$$

Let $\mathcal{I}$ be the Pfaffian system on $\mathcal{F}$ generated (as a differential ideal) by θ_0 and θ_1 . We will later develop methods for constructing integral submanifolds of $\mathcal{I}$ (when $X = \mathbb{C}H^n$, for small values of α) which are based on a close examination of the structure of $\mathcal{I}$ as an algebraic ideal. Thus, we need the algebraic generators of $\mathcal{I}$. We compute

$$\begin{aligned} d\theta_0 &\equiv -\omega_j^{2n} \wedge \omega^j, \\ d\theta_1 &\equiv \omega_j^{2n} \wedge \omega_k^{2n} J_j^k + \alpha\omega_k^{2n} J_j^k \wedge \omega^j + \Phi_{2n-1}^{2n}, \end{aligned}$$

modulo θ_0, θ_1 , where $1 \leq j, k \leq 2n-2$. (In simplifying the second equation, we use the relation $\omega_j^{2n-1} = \omega_k^{2n} J_j^k$, which is a consequence of (5).) For convenience, introduce the notation

$$\psi_j := \omega_j^{2n}, \quad 1 \leq j \leq 2n-2.$$

Then, using these abbreviations and the formula for the curvature 2-forms, the generator 2-forms of $\mathcal{I}$ can be expressed as

$$\begin{aligned} \Theta_0 &:= -\psi_j \wedge \omega^j, \\ \Theta_1 &:= (\psi_j - \alpha\omega^j) \wedge \psi_k J_j^k - 2c\Omega \end{aligned}$$

Note that, modulo the 1-forms of $\mathcal{I}$, Ω is congruent to

$$\Omega' := \omega^1 \wedge \omega^2 + \dots + \omega^{2n-3} \wedge \omega^{2n-2}.$$

One can show that, for any $n \geq 2$, the exterior differential system $\mathcal{I}$ is involutive, with nonzero Cartan characters $s_1 = s_2 = \dots = s_{n-1} = 2$ (see, e.g., [3] for definitions). Thus, Hopf hypersurfaces in X depend locally on specifying 2 real functions of $n-1$ real variables. Our aim in the next section is to give a concrete (and global) realization of this abstract count, in the hyperbolic case.

2. HOPF HYPERSURFACES WITH REAL CHARACTERISTICS

From now on assume that $X = \mathbb{CH}^n$ and let $c = -1/r^2$. Moreover, assume that $|\alpha| < 2/r$ and let $\phi \in (-\pi/2, \pi/2)$ be the unique angle such that

$$\alpha = (2/r) \sin \phi.$$

Our aim in this section is to define a pair of characteristic foliations for integral submanifolds of $\mathcal{I}$, and to show how to construct the Hopf hypersurface M in terms of data associated to the characteristics.

Notice that the above 2-forms Θ_0, Θ_1 are each expressed as a sum of $2n-2$ wedge products of pairs of 1-forms. By linearly combining Θ_0 and Θ_1 , we can produce equivalent generators which are much lower in rank, namely

$$\begin{aligned} \Theta_1 \pm \frac{2}{r} \cos \phi \Theta_0 = \\ 2 \sum_{i=1}^{n-1} (\psi_{2i-1} - \frac{1}{r}(\sin \phi \omega^{2i-1} \pm \cos \phi \omega^{2i})) \wedge (\psi_{2i} - \frac{1}{r}(\sin \phi \omega^{2i} \mp \cos \phi \omega^{2i-1})). \end{aligned}$$

The factors in these $n-1$ wedge products will have special significance in what follows, so we will introduce the notation

$$\kappa_j^\pm := \psi_j - \frac{1}{r}(\sin \phi \omega^j \pm \cos \phi \omega^{\bar{j}}), \quad 1 \leq j \leq 2n-2,$$

where

$$\omega^{\bar{j}} = \begin{cases} \omega^{j+1}, & \text{for } j \text{ odd,} \\ -\omega^{j-1} & \text{for } j \text{ even.} \end{cases}$$

Then we may take $\sum_{i=1}^{n-1} \kappa_{2i-1}^+ \wedge \kappa_{2i}^+$ and $\sum_{i=1}^{n-1} \kappa_{2i-1}^- \wedge \kappa_{2i}^-$ as generator 2-forms for $\mathcal{I}$, in place of Θ_0 and Θ_1 .

We define two Pfaffian systems of rank $2n$ on $\mathcal{F}$, given by

$$\mathcal{M}^\pm = \{\theta_0, \theta_1, \kappa_1^\pm, \dots, \kappa_{2n-2}^\pm\}.$$

These are the *characteristic systems* of $\mathcal{I}$, so called because a $2n-2$ -dimensional integral hyperplane $E \subset T_u \mathcal{F}$ belongs to the characteristic variety of $\mathcal{I}$ (see §4.6 in [3]) if and only if either the 1-forms κ_j^+ or the 1-forms κ_j^- restrict to be linearly dependent on E . (If $|\alpha| > 2/r$, or $X = \mathbb{CP}^n$, the complexified characteristic variety of $\mathcal{I}$ has no real points, and thus the system $\mathcal{I}$ is elliptic.)

Within each characteristic system, there is a smaller system which is *completely integrable*, i.e., it satisfies the Frobenius integrability condition. If we define

$$\kappa_0^\pm := \theta_1 \mp \frac{2}{r} \cos \phi \theta_0 = \omega_{2n-1}^{2n} - \frac{2}{r}(\sin \phi \omega^{2n-1} \pm \cos \phi \omega^{2n}),$$

then the systems

$$\mathcal{K}^\pm = \{\kappa_0^\pm, \kappa_1^\pm, \dots, \kappa_{2n-2}^\pm\}$$

are each completely integrable Pfaffian systems on $\mathcal{F}$. Indeed,

$$d\kappa_0^\pm \equiv 2 \sum_{i=1}^{n-1} \kappa_{2i-1}^\pm \wedge \kappa_{2i}^\pm \quad \text{mod } \kappa_0^\pm, \quad (7)$$

while

$$d\kappa_j^+ = -\kappa_k^\pm \wedge \omega_j^k + \omega_j^{2n} \wedge \kappa_0^\pm + \frac{1}{r}(\sin \phi \omega^{2n} \mp \cos \phi \omega^{2n-1}) \wedge \kappa_j^\pm - (\sin \phi \omega^{2n-1} \pm \cos \phi \omega^{2n}) \wedge \kappa_j^\pm.$$

The systems $\mathcal{K}^+$ and $\mathcal{K}^-$ have rank $2n - 1$; thus, applying the Frobenius Theorem shows that $\mathcal{F}$ is foliated by codimension- $(2n - 1)$ integrals of each system. Let L^+ and L^- be the leaf spaces for each foliation and let $q^\pm : \mathcal{F} \rightarrow L^\pm$ take a point in $\mathcal{F}$ to the unique maximal leaf through that point. Then we have the following result, to be proven in §3.2:

Proposition 1. *The leaf spaces $L^\pm$ can be identified with the standard sphere S^{2n-1} in a way such that the maps $q^\pm : \mathcal{F} \rightarrow S^{2n-1}$ are smooth submersions.*

Now let $\Sigma^{2n-1} \subset \mathcal{F}$ be an integral manifold of $\mathcal{I}$ satisfying the independence condition. Then clearly the 1-forms $\kappa_0^\pm$ pull back to be zero on Σ , as do the 2-forms given by the right-hand side of (7). This implies that the characteristic systems $\mathcal{K}^\pm$ each restrict to Σ to be of rank at most $n - 1$.

Lemma 2. *The restrictions of the system $\mathcal{K}^\pm$ to Σ have rank exactly $n - 1$ at each point.*

Proof. Suppose that $\kappa^\pm = T^\pm \omega$ when restricted to Σ , where we define vector-valued 1-forms $\omega = (\omega^1, \dots, \omega^{2n-2})$ and $\kappa^\pm$ similarly. Then the vanishing of Θ_0 on Σ implies that T^+ and T^- are transposes of one another. However, because the span on $\mathcal{F}$ of $\{\kappa_j^+, \kappa_j^-\}$ is the same as $\{\psi_j, \omega^j\}$, the ranks of T^+ and T^- must add up to $2n - 2$. Hence, each has rank $n - 1$. $\square$

It follows that Σ is foliated in two ways, by n -dimensional integral manifolds of $\mathcal{K}^+$ and $\mathcal{K}^-$, and the restrictions to Σ of the maps q^+ and q^- each have rank $n - 1$.

The equation (7) implies that on each leaf space $L^\pm$ there is a contact distribution whose annihilator 1-forms pull back via $q^\pm$ to be multiples of $\kappa_0^\pm$. (For a general criterion for the existence of well-defined exterior differential systems on quotient manifolds, given in terms of semibasic 1-forms on the total space, see Prop. 6.1.19 in [3].) Hence, the images of Σ under q^+ and q^- are $(n - 1)$ -dimensional immersed contact manifolds in the leaf spaces. (In §3.2 we will give a geometric interpretation of the contact condition in these spaces.) It is this ‘data’, the images $q^\pm(\Sigma)$, which we will use to recover the Hopf hypersurface. For simplicity, we consider here only the case where the contact manifolds are embedded.

Theorem 3. *Let $N_1 \subset L^+$ and $N_2 \subset L^-$ be Legendrian submanifolds of dimension $n - 1$, and let $R \subset \mathcal{F}$ be the intersection of their inverse images under q^+ and q^- respectively. Then R is a smooth n^2 -dimensional integral manifold of $\mathcal{I}$. Furthermore, if U is an open subset of R on which the independence condition holds, then $\rho(U) \subset \mathbb{CH}^n$ is an immersed Hopf hypersurface with Hopf principal curvature α .*

Proof. First, we note that the following 1-forms comprise a coframe on $\mathcal{F}$:

$$\omega^1, \dots, \omega^{2n-1}, \theta_0, \theta_1, \psi_1, \dots, \psi_{2n-2}, \omega_j^{2i},$$

where $1 \leq i \leq n - 1$ and $1 \leq j < 2i$. However, a coframe better-adapted to the two foliations of $\mathcal{F}$ is given by

$$\kappa_0^+, \kappa_0^-, \dots, \kappa_{2n-2}^+, \kappa_{2n-2}^-, \omega^{2n-1}, \omega_j^{2i}.$$

Since $N_1 \subset L^+$ is a smooth codimension- n submanifold, $P = (q^+)^{-1}(N_1)$ is a smooth codimension- n submanifold of $\mathcal{F}$. Moreover, because the generators of $\mathcal{K}^+$ span the semibasic forms for q^+ , these 1-forms satisfy n homogeneous linear equations when pulled back to P . (Of course, one of these equations is that $\kappa_0^+ = 0$.) Therefore, the generators κ_0^-, κ_j^- of $\mathcal{K}^-$

pull back to be linearly independent on P . Because these 1-forms span the semibasic forms for q^- , it follows that q^- restricts to P to be a surjective submersion. (In fact, the image under q^- of any maximal leaf of $\mathcal{K}^+$ is all of L^- .) Hence $R = P \cap (q^-)^{-1}(N_2)$ is a smooth integral manifold of $\mathcal{I}$, of codimension $2n$ in $\mathcal{F}$.

Assume that the independence condition is satisfied on $U \subset R$. Because the semibasic forms for ρ are spanned by $\omega^1, \dots, \omega^{2n}$ and $\omega^{2n} = \theta_0$ pulls back to be zero on R , then the restriction of ρ to U has rank $2n - 1$. It follows that $\rho(U)$ is an immersed hypersurface in $\mathbb{CH}^n$. It remains to show that this hypersurface is Hopf.

Given any $u \in U$, ρ is locally a submersion onto an embedded hypersurface M containing $x = \rho(u)$. Let $\Sigma \subset U$ be a $(2n - 1)$ -dimensional submanifold containing u , and satisfying the independence condition. Then Σ is the image of an adapted unitary frame field $(e_1, \dots, e_{2n})$ defined on M . Because θ_0 and θ_1 pull back to be zero on Σ , it follows that e_{2n} is normal to the hypersurface, and the structure vector e_{2n-1} is principal with principal curvature α , respectively. $\square$

Proposition 4. *Let R be as in Theorem 3. Then the rank of the restriction of ρ to R is at least n at each point.*

Proof. On R the 1-forms κ_j^+ satisfy $n - 1$ independent homogeneous linear equations, and the same is true for the κ_j^- . Write these linear relations in the form

$$A\kappa^+ = 0, \quad B\kappa^- = 0,$$

where A, B are $(n - 1) \times (2n - 2)$ matrices of rank $n - 1$ whose entries are functions on R , and we group the forms $\kappa_j^\pm$ into vector-valued 1-forms κ^+, κ^- with $2n - 2$ components each. Using the formulas for the $\kappa_j^\pm$ in terms of the canonical and connection forms of $\mathcal{F}$, the above relations imply that

$$\begin{pmatrix} A & \frac{\cos \phi}{r} A \\ B & -\frac{\cos \phi}{r} B \end{pmatrix} \begin{bmatrix} \psi - \frac{\sin \phi}{r} \omega \\ \tilde{J}\omega \end{bmatrix} = 0, \quad (8)$$

where ψ has components ψ_j , ω has components ω^j for $1 \leq j \leq 2n - 2$, and $\tilde{J}$ is the submatrix of J obtained by deleting the last two rows and columns. Any linear relation that holds among the pullbacks of the ω^j to R arises by linearly combining the rows of the matrix on the left in (8) to obtain a row with the first $2n - 2$ entries equal to zero. If we let k be the rank of the square matrix $\begin{pmatrix} A \\ B \end{pmatrix}$, then the number of linear relations among the ω^j is at most $2n - 2 - k$. It follows that the number of linear independent 1-forms among $\omega^1, \dots, \omega^{2n-1}$ restricted to R is at least $k + 1$, which is at least n . $\square$

Of course, for generic pairs of contact submanifolds N_1, N_2 we expect the rank of ρ to be equal to $2n - 1$ on an open dense set in R . For the case $n = 2$, we will express this genericity condition in concrete form at the end of §4.

Proposition 5. *Let N_1, N_2 and R be as in Theorem 3. Assume in addition that N_1 and N_2 are closed, and the independence condition holds on all of R . Then $M = \rho(R)$ is a complete Hopf hypersurface in $\mathbb{CH}^n$.*

Proof. Since R is the intersection of closed sets $(q^+)^{-1}(N_1)$ and $(q^-)^{-1}(N_2)$, then R is closed. We will show that M is closed.

Let p_k be a sequence of points in M converging to $\bar{p} \in \mathbb{CH}^n$. Let $\bar{B}$ be a geodesic ball centered at $\bar{p}$, such that $\mathcal{F}$ is trivial on an open set containing $\bar{B}$. Then $\rho^{-1}(\bar{B})$ is a compact set, diffeomorphic to $\bar{B} \times U(n)$. Choose a sequence $q_k \in R$ such that $\rho(q_k) = p_k$. Then for k

sufficiently large, the points q_k lie in $\rho^{-1}(\overline{B})$. Thus, there is a subsequence converging to a point $\bar{q} \in R$. Then by continuity of ρ , $\bar{p} = \rho(\bar{q})$ belongs in M .

Because M is a closed submanifold of the complete space $\mathbb{CH}^n$, M is also complete. $\square$

3. GEOMETRY OF THE LEAF SPACES

3.1. The Hopf Fibration and Moving Frames. In this section we review the geometry that $\mathbb{CP}^n$ and $\mathbb{CH}^n$ inherit via the Hopf fibration. We will later use this fibration to establish results about the leaf spaces discussed in §2, and to construct concrete examples of Hopf hypersurfaces in $\mathbb{CH}^n$.

On $\mathbb{C}^{n+1}$ define the real quadratic form

$$\langle \mathbf{z}, \mathbf{z} \rangle = |z_1|^2 + \cdots + |z_n|^2 + \epsilon |z_0|^2, \quad \epsilon = \pm 1,$$

and let $Q \subset \mathbb{C}^{n+1}$ be the quadric hypersurface defined by $\langle \mathbf{z}, \mathbf{z} \rangle = \epsilon r^2$ for $r > 0$. Let Q have the metric given by restricting this quadratic form; this metric will be Riemannian if $\epsilon = 1$ and Lorentzian if $\epsilon = -1$. The *Hopf fibration* $\pi : Q \rightarrow X$ is the quotient by the isometric action $\mathbf{z} \mapsto e^{i\theta}\mathbf{z}$ of S^1 on Q . When $\epsilon = +1$, X is $\mathbb{CP}^n(r)$, and when $\epsilon = -1$, X is $\mathbb{CH}^n(r)$. We endow X with the unique Riemannian metric such that the Hopf fibration is a (semi)-Riemannian submersion. The complex structure on X is also inherited via this submersion.

We say that an orthogonal basis $\hat{\mathbf{e}}_0, \hat{\mathbf{e}}_1, \dots, \hat{\mathbf{e}}_{2n}$ for $T_{\mathbf{z}}Q$ is an *adapted unitary frame* at $\mathbf{z}$ if, as vectors in $\mathbb{C}^{n+1}$, the members of the frame satisfy

$$\hat{\mathbf{e}}_0 = \frac{i}{r}\mathbf{z}, \quad \hat{\mathbf{e}}_2 = i\hat{\mathbf{e}}_1, \quad \hat{\mathbf{e}}_4 = i\hat{\mathbf{e}}_3, \dots \quad (9)$$

and $\langle \hat{\mathbf{e}}_j, \hat{\mathbf{e}}_j \rangle = 1$ for $1 \leq j \leq 2n$. (Note that $\langle \hat{\mathbf{e}}_0, \hat{\mathbf{e}}_0 \rangle = \epsilon$.) Let $\mathcal{G}$ be the sub-bundle of the general linear frame bundle of Q whose fiber at $\mathbf{z}$ consists of all adapted unitary frames for $T_{\mathbf{z}}Q$. Then the structure group of $\mathcal{G}$ is $U(n)$. A key observation, which we will make use of below in proving Proposition 1, is that $\mathcal{G}$ can be identified with a matrix Lie group, by taking the vectors $\frac{1}{r}\mathbf{z}, \hat{\mathbf{e}}_1, \hat{\mathbf{e}}_3, \dots, \hat{\mathbf{e}}_{2n-1}$ as columns in an $(n+1) \times (n+1)$ complex-valued matrix. Thus $\mathcal{G}$ is identified with $U(n+1)$ when $\epsilon = 1$ or with $U(1, n)$ when $\epsilon = -1$.

We define a submersion $\Pi : \mathcal{G} \rightarrow \mathcal{F}$ that sends an adapted unitary frame $(\hat{\mathbf{e}}_0, \hat{\mathbf{e}}_1, \hat{\mathbf{e}}_2, \dots, \hat{\mathbf{e}}_{2n})$ at $\mathbf{z}$ to the unitary frame $(\pi_*\hat{\mathbf{e}}_1, \pi_*\hat{\mathbf{e}}_2, \dots, \pi_*\hat{\mathbf{e}}_{2n})$ at $\pi(\mathbf{z})$. Conversely, given a unitary frame $(e_1, \dots, e_{2n})$ at $x \in X$ and a point $\mathbf{z} \in Q$ such that $\pi(\mathbf{z}) = x$, there is a unique adapted unitary frame at $\mathbf{z}$ such that $\pi_*\hat{\mathbf{e}}_j = e_j$; we will refer to this as the *horizontal lift* at $\mathbf{z}$ of $(e_1, \dots, e_{2n})$. Similarly, given a vector field V on an open set $U \subset X$, we may define a vector field V^H on $\pi^{-1}(U) \subset Q$ such that V^H is orthogonal to the fibers of π , and $\pi_*(V^H)_{\mathbf{z}} = V_{\pi(\mathbf{z})}$ for each $\mathbf{z} \in \pi^{-1}(U)$; this V^H is called the *horizontal lift* of V .

On $\mathcal{G}$, we regard $\mathbf{z}$ (the basepoint map) and $\hat{\mathbf{e}}_\alpha$ as $\mathbb{C}^{n+1}$ -valued functions. We define 1-forms η^α on $\mathcal{G}$ such that

$$d\mathbf{z} = \hat{\mathbf{e}}_\alpha \eta^\alpha. \quad (10)$$

(In what follows, we let $0 \leq \alpha, \beta \leq 2n$ and $1 \leq j, k, \ell, m \leq 2n$.) Multiplying by i/r gives

$$d\hat{\mathbf{e}}_0 = -\frac{1}{r^2}\mathbf{z}\eta^0 + \frac{1}{r}\hat{\mathbf{e}}_j J_k^j \eta^k,$$

where J is defined by (1). We also define 1-forms η_k^j on $\mathcal{G}$ by resolving the derivatives of the frame vectors:

$$d\hat{\mathbf{e}}_j = \hat{\mathbf{e}}_k \eta_j^k - \frac{\epsilon}{r^2}\mathbf{z}\eta^j - \frac{\epsilon}{r}\hat{\mathbf{e}}_0 J_k^j \eta^k. \quad (11)$$

(The last two terms are deduced by differentiating $\langle \mathbf{z}, \hat{\mathbf{e}}_j \rangle = 0$ and $\langle \hat{\mathbf{e}}_0, \hat{\mathbf{e}}_j \rangle = 0$.) Computing $d\langle \hat{\mathbf{e}}_j, \hat{\mathbf{e}}_k \rangle = 0$ shows that the η_k^j are skew-symmetric, while differentiating (9) gives

$$J_\ell^k \eta_j^\ell = \eta_\ell^k J_j^\ell. \quad (12)$$

We note that there are no further relations among these 1-forms; in fact, the forms η^α and η_k^j (for, say, j even and $k < j$) together comprise a coframe on $\mathcal{G}$. In fact, these are a basis for the left-invariant 1-forms when $\mathcal{G}$ is regarded as a Lie group.

The structure equations for the coframe on $\mathcal{G}$ are obtained by taking exterior derivatives of the defining equations for these 1-forms. Differentiating (10) gives the structure equations

$$d \begin{bmatrix} \eta^0 \\ \eta^j \end{bmatrix} = - \begin{pmatrix} 0 & -\frac{\epsilon}{r} J_j^k \eta^j \\ \frac{1}{r} J_k^j \eta^k & \eta_k^j \end{pmatrix} \wedge \begin{bmatrix} \eta^0 \\ \eta^k \end{bmatrix}. \quad (13)$$

while differentiating (11) leads to

$$d\eta_k^j = -\eta_\ell^j \wedge \eta_k^\ell + \frac{\epsilon}{r^2} (J_\ell^j \eta^\ell \wedge J_m^k \eta^m + \eta^j \wedge \eta^k). \quad (14)$$

Next, we need to calculate the pullbacks under Π of the canonical and connection 1-forms on $\mathcal{F}$.

Lemma 6. $\Pi^* \omega^j = \eta^j$ and $\Pi^* \omega_k^j = \eta_k^j - \frac{1}{r} J_k^j \eta^0$.

Proof. Let $\hat{f} = (\hat{\mathbf{e}}_0, \dots, \hat{\mathbf{e}}_{2n})$ be an arbitrary section of $\mathcal{G}$, defined on an open set $\hat{U} \subset Q$. Then (10) implies that the 1-forms $\hat{f}^* \eta^\alpha$ are dual to the frame vectors $\hat{\mathbf{e}}_\alpha$, i.e.,

$$\mathbf{v} = \left(\mathbf{v} \lrcorner \hat{f}^* \eta^\alpha \right) \hat{\mathbf{e}}_\alpha, \quad \forall \mathbf{v} \in T_z Q, \ z \in \hat{U}. \quad (15)$$

Hence, the 1-forms η^j on $\mathcal{G}$ are the pullbacks of the canonical 1-forms on the general frame bundle of Q .

Now let $f = (e_1, \dots, e_{2n})$ be an arbitrary section of $\mathcal{F}$, defined on an open set $U \subset X$, and let $\sigma : U \rightarrow Q$ be an arbitrary lift (i.e., $\pi \circ \sigma$ is the identity on U). Let $\hat{\mathbf{e}}_j$ be horizontal lifts of the e_j , and let $\hat{\mathbf{e}}_0$ be such that $(\hat{\mathbf{e}}_0, \dots, \hat{\mathbf{e}}_{2n})$ is an adapted unitary frame on $\sigma(U)$. Use pushforward by the S^1 action on Q (which preserves horizontality) to extend this frame to a section $\hat{f}$ defined on an open set $\hat{U}$ containing $\sigma(U)$. These maps are summarized by the following commutative diagram.

$$\begin{array}{ccc} Q \supset \hat{U} & \xrightarrow{\hat{f}} & \mathcal{G} \\ \sigma \uparrow \downarrow \pi & & \downarrow \Pi \\ \mathbb{C}H^n \supset U & \xrightarrow{f} & \mathcal{F} \end{array}$$

For any vector $\mathbf{v} \in T_z Q$, $z \in \hat{U}$, we can decompose $\mathbf{v}$ as in (15). By applying π_* to each side, we conclude that

$$\mathbf{v} \lrcorner \hat{f}^* \eta^j = (\pi_* \mathbf{v}) \lrcorner f^* \omega^j.$$

Using the commutative diagram, we obtain

$$\mathbf{v} \lrcorner \hat{f}^* \eta^j = \mathbf{v} \lrcorner (f \circ \pi)^* \omega^j = \mathbf{v} \lrcorner (\Pi \circ \hat{f})^* \omega^j,$$

and conclude that $\hat{f}^*(\eta^j - \Pi^* \omega^j) = 0$. Since f and σ are arbitrary, then $\Pi^* \omega^j = \eta^j$.

Similarly, because the matrix in (13) gives the connection forms for the Levi-Civita connection $\widehat{\nabla}$ on Q , we have

$$\widehat{\nabla}_{\mathbf{v}} \hat{\mathbf{e}}_j = (\mathbf{v} \lrcorner J_k^j \hat{f}^* \eta^k) \hat{\mathbf{e}}_0 + (\mathbf{v} \lrcorner \hat{f}^* \eta_j^k) \hat{\mathbf{e}}_k$$

for any section $\hat{f}$ of $\mathcal{G}$. Then applying π_* to both sides, and using the Riemannian submersion property that $\pi_* \left(\widehat{\nabla}_{V^H} W^H \right) = \nabla_V W$ for any vector fields V, W on X , we conclude that

$$\Pi^* \omega_k^j = \eta_k^j - \frac{1}{r} J_k^j \eta^0.$$

□

We note that by pulling back equation (3) via Π and using the results of Lemma 6 we can calculate the curvature forms given by (4).

3.2. Leaf Spaces and Spheres.

Proof of Proposition 1. We now assume that $\epsilon = -1$ and let $1 \leq j, k \leq 2n - 2$. Let $\widehat{\mathcal{K}}^\pm$ be the Pfaffian systems on $\mathcal{G}$ spanned by the pullbacks, via Π , of the characteristic systems $\mathcal{K}^\pm$ on $\mathcal{F}$, i.e., $\widehat{\mathcal{K}}^\pm$ is spanned by the 1-forms

$$\hat{\kappa}_0^\pm := \Pi^* \kappa_0^\pm = \eta_{2n-1}^{2n} - \frac{1}{r} \eta^0 - \frac{2}{r} (\sin \phi \eta^{2n-1} \pm \cos \phi \eta^{2n})$$

and

$$\hat{\kappa}_j^\pm := \Pi^* \kappa_j^\pm = \eta_j^{2n} - \frac{1}{r} (\sin \phi \eta^j \pm \cos \phi \eta^{\bar{j}}).$$

The Pfaffian systems $\widehat{\mathcal{K}}^\pm$ satisfy the Frobenius condition, and maximal integral manifolds of $\widehat{\mathcal{K}}^\pm$ are in 1-to-1 correspondence, via Π , with those of $\mathcal{K}^\pm$. However, the 1-forms $\hat{\kappa}_0^\pm$ and $\hat{\kappa}_j^\pm$ are left-invariant 1-forms on $\mathcal{G}$, and thus the maximal integral manifolds of $\widehat{\mathcal{K}}^\pm$ are left cosets of codimension- $(2n - 1)$ connected Lie subgroups $\mathcal{H}^\pm \subset \mathcal{G}$. We give the leaf spaces $L^\pm$ a manifold structure by identifying them with the homogeneous spaces $\mathcal{G}/\mathcal{H}^\pm$; then it is automatic that the quotient maps $q^\pm$ are smooth submersions.

It remains to identify the spaces $L^\pm$ as spheres. Let $\mathcal{V}$ be the cone of nonzero null vectors (with respect to $\langle, \rangle$) in $\mathbb{C}^{n+1}$. The set $\mathbb{P}\mathcal{V}$ of complex null lines in $\mathbb{C}^{n+1}$ is the image of $\mathcal{V}$ under the projectivization map π . We identify $\mathbb{P}\mathcal{V}$ with the unit sphere $S^{2n-1} \subset \mathbb{C}^n$ since, in terms of homogeneous coordinates $[z_0, z_1, \dots, z_n]$ on $\mathbb{CP}^n$, $\mathbb{P}\mathcal{V}$ lies entirely in the domain of the affine coordinates defined by $w_1 = z_1/z_0, \dots, w_n = z_n/z_0$, and the image of $\pi(\mathcal{V})$ is the codimension-one set in $\mathbb{C}^n$ defined by $|w_1|^2 + \dots + |w_n|^2 = 1$.

Next, define maps $\mathbf{g}^\pm : \mathcal{G} \rightarrow \mathcal{V}$ by

$$\mathbf{g}^\pm = \hat{\mathbf{e}}_0 - (\sin \phi \hat{\mathbf{e}}_{2n-1} \pm \cos \phi \hat{\mathbf{e}}_{2n}). \quad (16)$$

Let $\mathbf{g}_\mathbb{C}^\pm = \pi \circ \mathbf{g}^\pm$ be the corresponding maps from $\mathcal{G}$ to S^{2n-1} . Because any null vector can be expressed as the sum of spacelike and timelike vectors, the maps $\mathbf{g}_\mathbb{C}^\pm$ are surjective. Moreover, the fibers of $\mathbf{g}_\mathbb{C}^+$ (respectively, $\mathbf{g}_\mathbb{C}^-$) are cosets of $\mathcal{H}^+$ (resp., $\mathcal{H}^-$). To see why, first note that each fiber of $\mathbf{g}_\mathbb{C}^+$ is acted on simply transitively by the isotropy subgroup of $\mathcal{G}$ preserving a null line in $\mathbb{C}^{n+1}$; in particular, such isotropy subgroups are connected. Then, differentiating

$\mathbf{g}^+$ shows that $\mathbf{g}_\mathbb{C}^+$ is constant along the cosets of $\mathcal{H}^+$:

$$d\mathbf{g}^+ = \frac{1}{r}\mathbf{g}^+(\sin\phi\eta^{2n} - \cos\phi\eta^{2n-1}) + \frac{i}{r}\mathbf{g}^+(\eta^0 - \sin\phi\eta^{2n-1} - \cos\phi\eta^{2n}) \\ + (\cos\phi\hat{\mathbf{e}}_{2n-1} - \sin\phi\hat{\mathbf{e}}_{2n})\hat{\kappa}_0^+ + (\cos\phi\hat{\mathbf{e}}_j - \sin\phi\hat{\mathbf{e}}_j)\hat{\kappa}_j^+. \quad (17)$$

(This follows by noticing that the first two terms are complex multiples of $\mathbf{g}^+$ while all remaining terms involve 1-forms in $\hat{\mathcal{K}}^+$.) Thus, each coset lies in a single fiber of $\mathbf{g}_\mathbb{C}^+$, but since that fiber is connected, the fiber consists of exactly one coset of $\mathcal{H}^+$. Therefore, $\mathbf{g}^+$ covers a bijective map $\gamma^+ : L^+ \rightarrow \mathbb{P}\mathcal{V} \cong S^{2n-1}$. We summarize this situation in the following commutative diagram.

$$\begin{array}{ccc} \mathcal{G} & \xrightarrow{\mathbf{g}^+} & \mathcal{V} \\ q^+ \circ \Pi \downarrow & \searrow \mathbf{g}_\mathbb{C}^+ & \downarrow \pi \\ L^+ & \xrightarrow{\gamma^+} & S^{2n-1} \end{array}$$

In addition, because the semibasic 1-forms $\hat{\kappa}_0^+, \dots, \hat{\kappa}_{2n-2}^+$ appear in (17) with linearly independent vector coefficients, the map $\gamma^+ : L^+ \rightarrow S^{2n-1}$ is a local diffeomorphism. Hence, L^+ is diffeomorphic to the sphere, and the same is true for L^- . $\square$

Once we identify the leaf spaces L^+ and L^- with the projectivized null cone, the contact structures on these spaces have a geometric interpretation.

Proposition 7. *Let $N \subset L^\pm$ be a submanifold, and let $\mathbf{n} : N \rightarrow \mathcal{V}$ be any lift of $\gamma^\pm|_N$. Then N is a Legendrian submanifold if and only if*

$$\langle d\mathbf{n}, \mathbf{in} \rangle = 0. \quad (18)$$

Note that the left-hand side of (18) is a real-valued differential 1-form on N , and that this condition is independent of the choice of lift $\mathbf{n}$. In fact, when we identify the projectivized null cone with S^{2n-1} , this proposition implies that the contact $(n-1)$ -planes are perpendicular to the fibers of the Hopf fibration.

Proof. Again, we prove the assertions for L^+ , the proof for L^- being similar. Let $\hat{q} = q^+ \circ \Pi : \mathcal{G} \rightarrow L^+$. By definition of the contact structure on L^+ , N is Legendrian if and only if $\hat{q}^{-1}(N)$ is an integral of the 1-form $\hat{\kappa}_0^+ = \Pi^*\kappa_0^+$.

Let $f : N \rightarrow \mathcal{G}$ be any lift of $\mathbf{n} : N \rightarrow \mathcal{V}$, so that $\mathbf{n} = \mathbf{g}^+ \circ f$. Then pulling (17) back by f gives

$$d\mathbf{n} = \frac{1}{r}\mathbf{n}f^*(\sin\phi\eta^{2n} - \cos\phi\eta^{2n-1}) + \frac{i}{r}\mathbf{n}f^*(\eta^0 - \sin\phi\eta^{2n-1} - \cos\phi\eta^{2n}) \\ + (\cos\phi\hat{\mathbf{e}}_{2n-1} - \sin\phi\hat{\mathbf{e}}_{2n})f^*\hat{\kappa}_0^+ + (\cos\phi\hat{\mathbf{e}}_j - \sin\phi\hat{\mathbf{e}}_j)f^*\hat{\kappa}_j^+, \quad (19)$$

where the vector-valued functions $\hat{\mathbf{e}}_j$ on $\mathcal{G}$ should be understood as being composed with f . By using the formula for $\mathbf{g}^+$ we obtain

$$\langle d\mathbf{n}, \mathbf{in} \rangle = f^*\hat{\kappa}_0^+.$$

Since f is arbitrary, the vanishing of the left-hand side is equivalent to $\hat{q}^{-1}(N)$ being an integral of $\hat{\kappa}_0^+$. $\square$

4. PARAMETRIC REPRESENTATIONS

Given two Legendrian submanifolds N_1, N_2 in S^{2n-1} , we wish to construct the Hopf hypersurface M of Theorem 3. Let R be as in Theorem 3 and let $\hat{R}$ be its inverse image under $\Pi : \mathcal{G} \rightarrow \mathcal{F}$. This is the intersection of the inverse images of N_1, N_2 under the maps $\mathbf{g}^+$ and $\mathbf{g}^-$. The Hopf hypersurface is the image of $\hat{R}$ under $\rho \circ \Pi$, the map that takes a point in the frame bundle $\mathcal{G}$ to the projectivization of the basepoint $\mathbf{z}$.

Let $\mathbf{n}_i : N_i \rightarrow \mathcal{V}$ be any lifts of N_i into the null cone. (We may choose unique lifts by requiring that the images lie in the intersection of $\mathcal{V}$ with the hyperplane where $z_0 = 1$.) We will determine the values of $\mathbf{g}^+, \mathbf{g}^-, \hat{\mathbf{e}}_0$ and $\mathbf{z}$ along $\hat{R}$, in terms of $\mathbf{n}_1, \mathbf{n}_2$ and an extra parameter λ . Because $\mathbf{g}^+$ (resp. $\mathbf{g}^-$) must lie in the complex line spanned by $\mathbf{n}^+$ (resp. $\mathbf{n}^-$), there are nonzero scalars μ_1, μ_2 such that

$$\mathbf{g}^+ = \mu_1 \mathbf{n}_1, \quad \mathbf{g}^- = \mu_2 \mathbf{n}_2 \quad (20)$$

These scalars are not arbitrary, since the intersection of a fiber of $\hat{q}^+$ with a fiber of $\hat{q}^-$ is a 3-dimensional submanifold of $\mathcal{G}$. In fact, each such submanifold intersects the fiber of $\rho \circ \Pi$ in a 2-dimensional torus.¹ Thus, only one additional real parameter, independent of local coordinates on N_1, N_2 , should remain on the image of $\hat{R}$ under $\rho \circ \Pi$.

The multiples μ_1, μ_2 are partially determined by the normalizations of the vectors $\mathbf{g}^\pm$. For example, (16) implies that $\mathbf{g}^+ + \mathbf{g}^- = 2(\hat{\mathbf{e}}_0 - \sin \phi \hat{\mathbf{e}}_{2n-1})$, so that $\langle \mathbf{g}^+ + \mathbf{g}^-, \mathbf{g}^+ + \mathbf{g}^- \rangle = -4 \cos^2 \phi$. Substituting (20) into equation gives

$$\langle \mu_1 \mathbf{n}_1, \mu_2 \mathbf{n}_2 \rangle = -2 \cos^2 \phi. \quad (21)$$

To facilitate factoring out the scalars, we introduce the sesquilinear form

$$\langle \mathbf{z}, \mathbf{w} \rangle_{\mathbb{C}} = -\overline{z_0} w_0 + \overline{\mu_1} w_1 + \dots + \overline{z_n} w_n, \quad (22)$$

which satisfies $\langle \mathbf{z}, \mathbf{w} \rangle = \operatorname{Re} \langle \mathbf{z}, \mathbf{w} \rangle_{\mathbb{C}}$. Define the function $\zeta : N_1 \times N_2 \rightarrow \mathbb{C}$ by

$$\zeta := \langle \mathbf{n}_1, \mathbf{n}_2 \rangle_{\mathbb{C}}. \quad (23)$$

Then (21) gives

$$\operatorname{Re}(\overline{\mu_1} \mu_2 \zeta) = -2 \cos^2 \phi. \quad (24)$$

Since the right-hand side must be nonzero, we restrict our attention to the open set $U \subset N_1 \times N_2$ where $\zeta \neq 0$.

From (16) one can calculate that

$$\hat{\mathbf{e}}_0 = \frac{1}{2}(1 + i \tan \phi) \mathbf{g}^+ + \frac{1}{2}(1 - i \tan \phi) \mathbf{g}^- = \frac{e^{i\phi} \mu_1}{2 \cos \phi} \mathbf{n}_1 + \frac{e^{-i\phi} \mu_2}{2 \cos \phi} \mathbf{n}_2. \quad (25)$$

Then the condition $\langle \hat{\mathbf{e}}_0, \hat{\mathbf{e}}_0 \rangle = -1$ implies that

$$\operatorname{Re}(e^{-2i\phi} \overline{\mu_1} \mu_2 \zeta) = -2 \cos^2 \phi.$$

Comparing with (24), we deduce that $\overline{\mu_1} \mu_2 \zeta = -2e^{i\phi} \cos \phi$. Hence, the coefficients of $\mathbf{n}_1, \mathbf{n}_2$ in (25) satisfy

$$\frac{e^{i\phi} \mu_1}{2 \cos \phi} \frac{e^{-i\phi} \mu_2}{2 \cos \phi} = -\frac{1 - i \tan \phi}{2 \zeta}.$$

¹This is the orbit of an $S^1 \times S^1$ action on $\mathcal{G}$. One copy of S^1 acts by rotating $\hat{\mathbf{e}}_1$ and $\hat{\mathbf{e}}_2$ in a circle, while the other acts by multiplying $\mathbf{z}$ by a unit modulus complex number at the same time as rotating $\hat{\mathbf{e}}_{2n-1}$ and $\hat{\mathbf{e}}_{2n}$ in a circle.

Suppose that there exists a smooth complex-valued function $\tau : N_1 \times N_2 \rightarrow \mathbb{C}$ such that $\tau^2 = \frac{1}{2}(1 - i \tan \phi)/\zeta$. (Equivalently, assume that a consistent branch can be chosen for $\sqrt{\zeta}$ on U .) Then $e^{i\phi}\mu_1 = 2 \cos \phi \overline{\lambda\tau}$ and $e^{-i\phi}\mu_2 = -2 \cos \phi \tau/\lambda$ for some nonzero complex parameter λ , and so

$$\hat{\mathbf{e}}_0 = \overline{\lambda\tau}\mathbf{n}_1 - \frac{\tau}{\lambda}\mathbf{n}_2. \quad (26)$$

Because $\mathbf{z} \in Q$ is a complex multiple of $\hat{\mathbf{e}}_0$, the image of $\hat{R}$ under $\rho \circ \Pi : \mathcal{G} \rightarrow \mathbb{CH}^n$ coincides with the image of $\hat{\mathbf{e}}_0$ under complex projectivization π . Note that this image does not depend on the argument of λ ; thus, the Hopf hypersurface $M \subset \mathbb{CH}^n$ is given, up to complex multiple, by the right-hand side of (26), and M is parametrized by local coordinates on U and $|\lambda|$. So, we may take λ to be real and positive; then using $\mathbf{z} = -(i/r)\hat{\mathbf{e}}_0$ gives the following mapping from $U \times \mathbb{R}^*$ into $\mathbb{C}^{n+1}$ which is a canonical lift of the Hopf hypersurface in to Q :

$$\mathbf{z} = \frac{1}{r} \left(-i\lambda\overline{\tau}\mathbf{n}_1 + i\frac{\tau}{\lambda}\mathbf{n}_2 \right) \quad (27)$$

Remark. One can show that the λ -coordinate curves on the lift correspond to the W -curves on M , i.e., the lines of curvature tangent to the structure vector W . Moreover, (27) shows that when we use affine coordinates $w_1 = z_1/z_0$, $w_2 = z_2/z_0, \dots$ to map M into the open unit ball in $\mathbb{C}^n$, the Legendrian submanifolds N_1, N_2 appear as limits of M on the ideal boundary S^{2n-1} of $\mathbb{CH}^n$ as λ approaches 0 and ∞ along the W -curves. It is also clear from (27) that each W -curve is contained in the complex line in $\mathbb{CP}^n$ spanned by its endpoints on the boundary. The intersection of $\mathbb{CH}^n$ with this line is a hyperbolic disc in which the W -curve has constant curvature α .

Note that for *arbitrary* given Legendrian submanifolds N_1, N_2 , the composition of the mapping (27) with projection into $\mathbb{CH}^n$ is not automatically of rank $2n - 1$. We end this section with a discussion of the case $n = 2$, in which we work out the rank condition explicitly.

Our starting ingredients are contact curves $\mathcal{C}_1, \mathcal{C}_2$ in S^3 . Suppose a curve $\mathcal{C}$ in $S^3 \subset \mathbb{C}^2$ is defined parametrically by complex coordinates $w_1(t) = e^{i\beta(t)} \cos \mu(t)$ and $w_2 = e^{i\gamma(t)} \sin \mu(t)$, and $\mathbf{n}(t) = [1, w_1(t), w_2(t)]$ is the lift into the null cone $\mathcal{V} \subset \mathbb{C}^3$. Applying the condition from Prop. 7 to this lift, we find that $\mathcal{C}$ is a contact curve if and only if

$$\beta' \cos^2 \mu + \gamma' \sin^2 \mu = 0. \quad (28)$$

This is an underdetermined ODE which, for example, may be solved for $\beta(t)$ given functions $\gamma(t)$ and $\mu(t)$.

Let $\mathcal{C}_1$ and $\mathcal{C}_2$ be contact curves defined respectively by solutions $\mu_1(s), \beta_1(s), \gamma_1(s)$ and $\mu_2(t), \beta_2(t), \gamma_2(t)$ of (28). The lifts are

$$\mathbf{n}_1(s) = \begin{bmatrix} 1 \\ e^{i\beta_1} \cos \mu_1 \\ e^{i\gamma_1} \sin \mu_1 \end{bmatrix}, \quad \mathbf{n}_2(t) = \begin{bmatrix} 1 \\ e^{i\beta_2} \cos \mu_2 \\ e^{i\gamma_2} \sin \mu_2 \end{bmatrix}.$$

and we compute

$$\zeta(s, t) = -1 + e^{i(\beta_2 - \beta_1)} \cos \mu_1 \cos \mu_2 + e^{i(\gamma_2 - \gamma_1)} \sin \mu_1 \sin \mu_2.$$

Proposition 8. *Let $u = \log \lambda$ for λ real and positive. Then the map taking (s, t, u) to the projection of the right-hand side of (27) into $\mathbb{CH}^2$ has rank 3 at points where $\zeta \neq 0$ and*

$$\operatorname{Im} \left(\frac{\partial^2 \zeta}{\partial s \partial t} - \frac{\sec^2 \phi}{\zeta} \frac{\partial \zeta}{\partial s} \frac{\partial \zeta}{\partial t} \right) \neq 0.$$

12

While the assumption that $\mathbf{n}_1(s)$ satisfies the contact condition of Prop. (7) implies that

$$\left\langle \frac{\partial \mathbf{n}_1}{\partial s}, \mathbf{n}_1 \right\rangle_{\mathbb{C}} = 0.$$

Proof of Prop. 8. It is sufficient to work with the projection of the right-hand side of (26), which differs from $\mathbf{z}$ by a complex constant. Differentiating (26) gives

$$\partial \hat{\mathbf{e}}_0 / \partial u = \lambda \bar{\tau} \mathbf{n}_1 + (\tau / \lambda) \mathbf{n}_2. \quad (29)$$

It follows from (23) that $\langle \partial \hat{\mathbf{e}}_0 / \partial u, \partial \hat{\mathbf{e}}_0 / \partial u \rangle = 1$. Thus, $\partial \hat{\mathbf{e}}_0 / \partial u$ is a spacelike vector in $\mathbb{C}^3$, and is linearly independent of complex multiples of the timelike vector $\hat{\mathbf{e}}_0$.

Next, we compute

$$\frac{\partial \hat{\mathbf{e}}_0}{\partial s} = \lambda \bar{\tau}_s \mathbf{n}_1 + \lambda \bar{\tau} \frac{d\mathbf{n}_1}{ds} - \frac{\tau_s}{\lambda} \mathbf{n}_2, \quad \frac{\partial \hat{\mathbf{e}}_0}{\partial t} = \lambda \bar{\tau}_t \mathbf{n}_1 - \frac{\tau_t}{\lambda} \mathbf{n}_2 - \frac{\tau}{\lambda} \frac{d\mathbf{n}_2}{dt}.$$

Let $\mathbf{P}$ denote projection onto the orthogonal complement of the complex span of $\hat{\mathbf{e}}_0$ and $\partial \hat{\mathbf{e}}_0 / \partial u$. (Note that $\mathbf{n}_1$ and $\mathbf{n}_2$ lie in this span, and the map $\mathbf{P}$ is $\mathbb{C}$ -linear.) Then $\mathbf{P}(\partial \hat{\mathbf{e}}_0 / \partial s) = \lambda \bar{\tau} \mathbf{P}(d\mathbf{n}_1 / ds)$ and $\mathbf{P}(\partial \hat{\mathbf{e}}_0 / \partial t) = -(\tau / \lambda) \mathbf{P}(d\mathbf{n}_2 / dt)$. We will compute conditions under which these projections are linearly independent over $\mathbb{R}$.

The fact that $\mathbf{n}_1(s)$ satisfies the contact condition of Prop. (7) implies

$$\left\langle \frac{d\mathbf{n}_1}{ds}, \mathbf{n}_1 \right\rangle_{\mathbb{C}} = 0.$$

Using this and (26) we obtain

$$\left\langle \frac{d\mathbf{n}_1}{ds}, \hat{\mathbf{e}}_0 \right\rangle_{\mathbb{C}} = -\frac{\tau}{\lambda} \frac{\partial \zeta}{\partial s}, \quad \left\langle \frac{d\mathbf{n}_1}{ds}, \frac{\partial \hat{\mathbf{e}}_0}{\partial u} \right\rangle_{\mathbb{C}} = \frac{\tau}{\lambda} \frac{\partial \zeta}{\partial s}.$$

Hence

$$\mathbf{P} \left(\frac{d\mathbf{n}_1}{ds} \right) = \frac{d\mathbf{n}_1}{ds} - \frac{\bar{\tau}}{\lambda} \frac{\partial \bar{\zeta}}{\partial s} \left(\hat{\mathbf{e}}_0 + \frac{\partial \hat{\mathbf{e}}_0}{\partial u} \right) = \frac{d\mathbf{n}_1}{ds} - 2\bar{\tau}^2 \frac{\partial \bar{\zeta}}{\partial s} \mathbf{n}_1.$$

Similarly, we compute

$$\mathbf{P} \left(\frac{d\mathbf{n}_2}{dt} \right) = \frac{d\mathbf{n}_2}{dt} - 2\tau^2 \frac{\partial \zeta}{\partial t} \mathbf{n}_2.$$

Because the range of $\mathbf{P}$ has real dimension 2, these two vectors will be linearly independent if and only if the imaginary part of their complex inner product (in the sense of (22)) is nonzero. By using the inner product values given by differentiating (23), we obtain

$$\left\langle \frac{d\mathbf{n}_1}{ds} - 2\bar{\tau}^2 \frac{\partial \bar{\zeta}}{\partial s} \mathbf{n}_1, \frac{d\mathbf{n}_2}{dt} - 2\tau^2 \frac{\partial \zeta}{\partial t} \mathbf{n}_2 \right\rangle_{\mathbb{C}} = \frac{\partial^2 \zeta}{\partial s \partial t} - \frac{\sec^2 \phi}{\zeta} \frac{\partial \zeta}{\partial s} \frac{\partial \zeta}{\partial t}.$$

□

CONCLUSION

As with the work of Aledo *et al* [1] on flat surfaces in S^3 , one could use the d'Alembert formula to study the Cauchy problem for Hopf hypersurfaces. (In this direction, Ryan and I [5] have shown that a Hopf hypersurface may be constructed which contains any given curve with zero holomorphic torsion in $\mathbb{CP}^2$ or $\mathbb{CH}^2$ as a principal curve.) Another interesting application of this technique would be the study of singularities of Hopf hypersurfaces, for example comparing the degenerations of hypersurfaces with small α with those of hypersurfaces with large α .

I thank Pat Ryan and Robert Bryant for helpful discussions and encouragement. I also thank the referees of earlier versions of this article for their comments and suggestions.
